Breathing Room: How the money moves (explained simply)

Oct 12, 2026 · @Marcus

The short answer

Monad is a network, MON is its coin, and MON is not tied to the pound. Monad is a blockchain: a shared, public computer where our pot lives. MON is the coin that network runs on, the way Bitcoin is the coin of the Bitcoin network. Its price moves up and down every day, like any crypto coin. It is not a stablecoin.

On the test network we build on, MON is free play money with no price at all. That's why the demo uses a made-up rate (£1 = 0.00001 MON) just so the screens can show pounds. Nothing about that rate is real.

We don't need to invent our own coin. For real pounds, the pot would hold a pound stablecoin: an existing token that a regulated company keeps worth exactly £1. Section 5 covers what to do before the deadline.

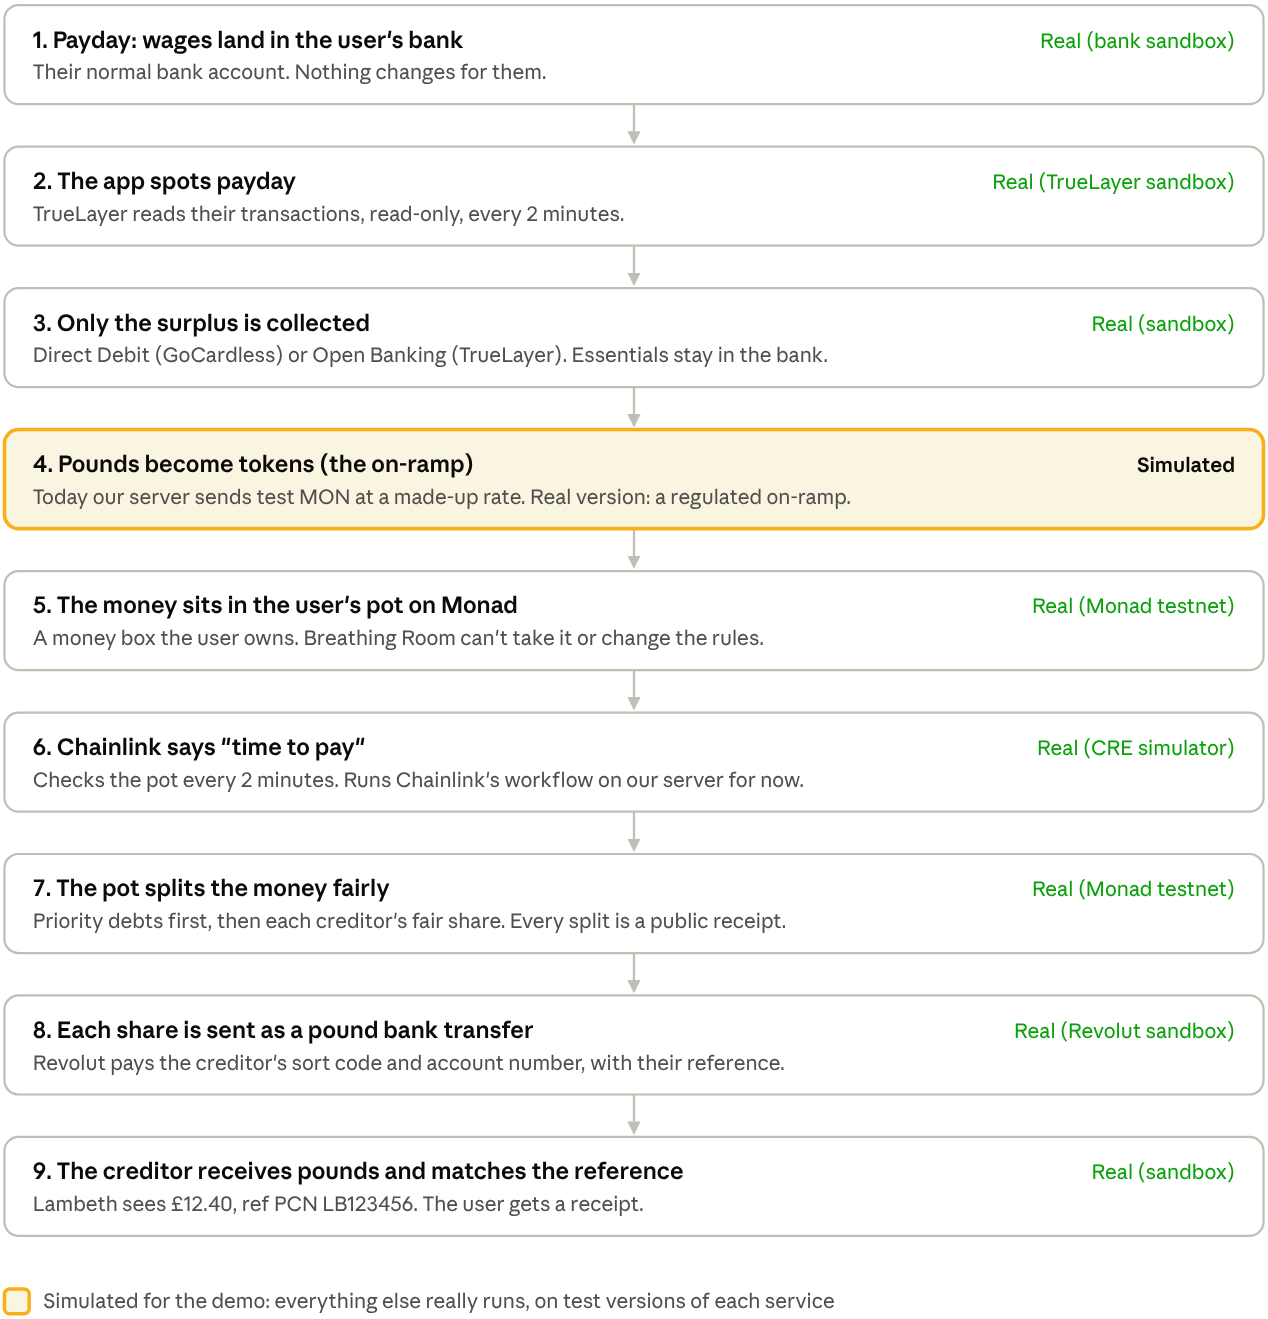

The words, explained like you're five

Word	What it is	Like...
Blockchain	A shared notebook that thousands of computers keep a copy of. Once something is written, nobody can rub it out.	A school register everyone can read but nobody can change
Monad	One particular blockchain. Very fast and very cheap to use.	One particular road
MON	Monad's own coin. Its price goes up and down.	The money the toll booths on that road take
Stablecoin	A token a regulated company keeps worth exactly £1 (or $1), backed by real money in a bank.	A gift card that's always worth exactly £1

Word	What it is	Like…
Testnet	A practice copy of Monad where coins are free and worth nothing. Where we build and demo.	A driving test centre
Mainnet	The real Monad, where coins are worth real money.	The real road
Pot	Our smart contract: a money box with rules, owned by the user. Pays essentials first, then creditors fairly.	A piggy bank that empties itself fairly on payday
Smart contract	A program that lives on the blockchain and runs exactly as written.	A vending machine: put money in, the rules decide what comes out
On-ramp / off-ramp	Services that swap bank pounds into tokens, and back.	The bureau de change at the airport

The whole money pipeline

From payday to creditor: only one step is simulated

☐ Simulated for the demo: everything else really runs, on test versions of each service

money pipeline · 9 steps, 1 simulated

Every step really runs on a test version of a real service, except step 4. Swapping pounds into tokens is faked by our server at a made-up rate, because the testnet coin has no real price. Step 8 is built and waits on the Revolut sandbox connection.

Real rates

On the real market, **1 MON is worth about £0.016**, so £1 buys about 60 MON (CoinGecko, The Block). Sources vary between £0.016 and £0.02, and it sits about 56% below its all-time high. Our demo rate (£1 = 0.00001 MON) is not that. It was picked so tiny amounts of free test MON could stand in for hundreds of pounds.

Three honest options:

Option	What it means	Verdict
Use MON at the real live rate	£495 surplus = about 30,000 MON. The testnet faucet only gives a few MON, so the demo can't hold realistic amounts. And in real life, debt money held in a coin that moves 50% would be unsafe.	No
Test pound token (1 token = £1)	Deploy a test "£" token on Monad testnet and a pot that holds it. Every number on screen is real pounds, no fake rate. Mirrors exactly how a real pound stablecoin would work.	Best for winning
Keep MON, explain it	Leave the demo as is and say plainly that the rate is a placeholder.	Fallback

What exists for real today: USDC (a dollar stablecoin) is already live on Monad (zerohash). I found no pound stablecoin on Monad yet; StraitsX plans Singapore and US dollar coins for 2027 (TokenPost). So in production the pot would hold USDC with a live £/$ rate, or a pound stablecoin once one launches on Monad.

Recommendation for winning

Switch the pot to a test pound token before the deadline. It removes the one confusing number in the demo (the fake MON rate), every amount on screen becomes real pounds, and it matches the production design judges will ask about. It's not "our own coin" in any business sense: it's a stand-in for a regulated pound stablecoin, the normal way to test one.

What changes: a token-holding version of the pot, a test £ token on Monad testnet, the Chainlink check pointed at the new pot, and the app, on-ramp and payout worker reading pounds 1:1. Nothing changes for users or in the flow above, except step 4 becomes "pounds become pound tokens, 1 for 1".

Order of work: finish the Revolut connection first (step 8, waiting on the Client ID), then the pound token. If time runs short, submit with MON and say the rate is a placeholder.

Say this in the pitch: "The pot holds pound tokens, one per pound, so every split is exact. In production that's a regulated stablecoin; USDC is already live on Monad. Fees are a fraction of a penny, so even a £5 token payment arrives whole."
